B

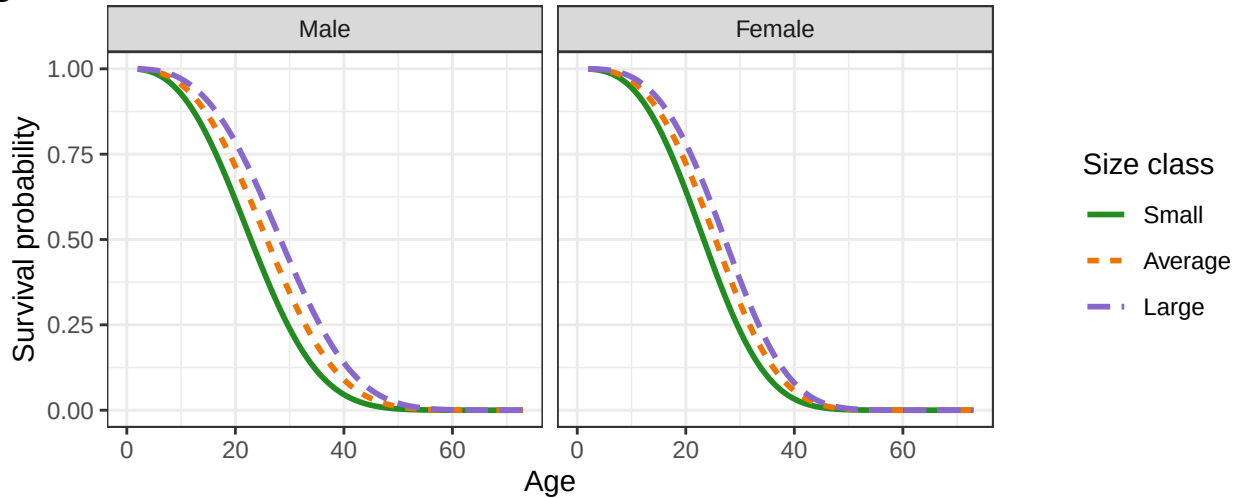

Figure 5. This demonstrates the separate and significant impact both sex and size has on aging. Panel A shows the plotted predicted values from the P4 model, under the assumption that the butterfly is of 'average size', to control the predictor of size, against the previously documented Kaplan–Meier curves. Panel B depicts P4 plotted separately by sex at three representative size values (categorized as small: one SD below mean size, average: mean size, and large: individuals one SD above mean size), showing that as size increased, aging was reduced (Fig. 6).
